Abstract

This is my notes when taking the class *Fundamentals of Pure Mathematics* at the University of Edinburgh. These notes do not follow the course lecture notes; instead, they are my thoughts and works inspired by the class. Terms like “Theorem, Proposition” are coined in Latin. Here is the list: theorema for theorem, Corollarium for corollary, Propositio for proposition, Definitio for definition, Coniectura for hypothesis (conjecture).

Chapter 1

Notation

- The `\mathbb{}` fonts are used to denote sets. (\mathbb{S} , \mathbb{Y} , etc.)
- $\mathbb{A} \succ \mathbb{B}$ denotes there exists a surjective function $f : A \rightarrow B$. \prec , \asymp denotes injective, bijective, respectively.
- e is used to denote the identity of a group.
- When there is no ambiguity, the notation for the operation of group is omitted. (i.e., $a \odot b = ab$). a^{-1} is used to denote the inverse of a .

Chapter 2

Analysis

Axioma 2.0.1 (The "Smallest" Infinite Set). A set \mathbb{S} is infinite iff $\mathbb{S} \succ \mathbb{N}$.

Observatio 2.0.1. Although FPM is a pure mathematic class with emphasis on rigor, no rigorous definition for the infinite set has been proposed. This definition/axiom is of my own conception.

Definitio 2.0.1 (Countable Set). A set \mathbb{S} is countable iff $\mathbb{N} \asymp \mathbb{S}$ (there exists a bijection $f : \mathbb{N} \rightarrow \mathbb{S}$).

Corollarium 2.0.1 (At Most Countable). *Let \mathbb{A} be an infinite set. $(\mathbb{A} \prec \mathbb{N})$ iff $(\mathbb{A} \asymp \mathbb{N})$.*

Proof. We want to prove $\mathbb{A} \prec \mathbb{N}$ is equivalent to $\mathbb{A} \asymp \mathbb{N}$. $\mathbb{A} \asymp \mathbb{N} \rightarrow \mathbb{A} \prec \mathbb{N}$ is by definition. We only need to prove the other direction; i.e., provided $\mathbb{A} \prec \mathbb{N}$, find a bijective function $h : \mathbb{A} \rightarrow \mathbb{N}$.

Let $f : \mathbb{A} \rightarrow \mathbb{N}$ be an injective mapping. If f is bijective, we are done. If f is injective but not bijective, let \mathbb{N}^- be the range of f . As \mathbb{A} is infinite, \mathbb{N}^- is also infinite. Let $f' : \mathbb{A} \rightarrow \mathbb{N}^-$ such that $f(a) = f'(a)$. f' is an bijective mapping.

Thus we only need to show there exists a mapping $g : \mathbb{N}^- \rightarrow \mathbb{N}$ that is bijective.

g can be constructed by such: sort \mathbb{N}^- and \mathbb{N} in ascending order. Let the first element in the sorted \mathbb{N}^- maps to the first in the sorted \mathbb{N} , the second to second, etc. As \mathbb{N}^- is infinite, g must be bijective.

Indeed $h = f' \circ g : \mathbb{A} \rightarrow \mathbb{N}$ is the bijective mapping we seek. Q.E.D.

Theorema 2.0.1 (List of Countable and Uncountable Sets). *Any of the following sets are countable.*

1. \mathbb{Z} and any of its infinite subsets.

2. \mathbb{R} and any of its infinite subsets.

3. If \mathbb{S} is countable, $\{\mathbb{S} \times \mathbb{S}\}, \{\mathbb{S} \times \mathbb{S} \times \cdots \times \mathbb{S}\}$ are also countable.

Chapter 3

Algebra

Definitio 3.0.1 (Group). Group is a set \mathbb{S} with an operation \odot that fulfills the following four properties:

1. Closure
2. Associativity: $(a \odot b) \odot c = a \odot (b \odot c)$;
3. Identity
4. Inverse

Theorema 3.0.1 (Consequence of the Definition). *There are many non-obvious properties that directly follows the definition.*

1. *General Associativity: Parenthesis does not matter, as long as the order is the same: $a \odot b \odot c \odot d \odot e \odot f \odot g \cdots = (a \odot ((b \odot c) \odot e (\odot f \odot g) \cdots)) = \cdots$*
2. *Order of Inverse: $(a \odot b)^{-1} = b^{-1} \odot a^{-1}$.*

Here are some examples of groups.

1. $\mathbb{S} = \{e\}$
2. $\mathbb{S} = \{e, a, b, c\}$. With the following operation: 1. All elements are their own inverse; 2. The group is abelian. 2. $a \odot b = c, a \odot c = b, b \odot c = a$.

Coniectura 3.0.1. These are some of my hypothesis and thoughts.

1. different properties of odd finite groups and even finite groups
2. If defining the revert of the operation \odot to be \oslash as such: $a \odot b = a \oslash b^{-1}$. What are the sets such that it would be a group under both \odot & \oslash ?

3. Can we have a set \mathbb{S} , such that under the operation \odot we have $\forall a, b \in \mathbb{S}, a \odot b = b \odot a$ but without associativity? (Community without associativity?)

Definitio 3.0.2 (Order of Group and element). The order of the group \mathbb{S} is $|\mathbb{S}|$ (How many elements it has).

The order of an element $s \in \mathbb{S}$ is the smallest integer i such that $s^i = e$. (If such i exists)

Definitio 3.0.3 (Cyclic Group). Let \mathbb{G} be a group and g one of its element. Considering the set:

$$\mathbb{S} = \{\cdots g^{-2}, g^{-1}, e, g, g^1, g^2 \cdots\}$$

If \mathbb{S} is finite, it is called a cyclic group. (It can be shown that it must be a subgroup of \mathbb{G}).
